## Description

### BACKGROUND OF THE INVENTION

#### Field of the Invention

The present invention relates to an ink-jet recording apparatus in which ink drops are ejected so as to be deposited on a surface of recording paper only when recording is required. In particular, the present invention relates to a small-sized high-density ink-jet recording apparatus produced through application of a micro-machining technique, and relates to a method for producing an ink-jet head as a main part of such an ink-jet recording apparatus.

#### Description of the Prior Art

Ink-jet recording apparatuses are advantageous in many points that noise is extremely low at the time of recording, high-speed printing can be made, the degree of freedom of ink is so high that inexpensive ordinary paper can be used, and so on. Among those ink-jet recording apparatuses, an ink-on-demand type apparatus in which ink drops are ejected only when recording is required has been the focus of attention because it is not necessary to recover ink drops unnecessary for recording.

In such an ink-on-demand type apparatus, as described, for example, in Japanese Patent Postexam. Publication No. Hei-2-51734, corresponding to US4339763A, a print head is constituted by: a plurality of nozzle openings arranged in parallel to each other to eject ink drops therefrom; a plurality of independent ejection chambers respectively communicated with the corresponding nozzle openings and each having walls one of which is partly formed to serve as a diaphragm; a plurality of piezoelectric elements respectively attached on the corresponding diaphragms so as to serve as electromechanical transducers; and a common ink cavity for supplying ink to the each of the ejection chambers. In such a print head, upon application of a printing pulse voltage to any one of the piezo electric elements, the diaphragm corresponding to the one piezoelectric element is mechanically distorted so that the volume of the ejection chamber corresponding to the diaphragm is reduced and the pressure in the chamber is increased instantaneously. As a result, an ink drop is ejected from the corresponding one of the nozzle openings toward recording paper.

In the aforementioned structure of the conventional ink-jet recording apparatus, however, much labor as well as much time are required for mounting such piezoelectric elements on the ejection chambers because the piezoelectric elements must be stuck onto the outside of the ejection chambers through glass or resin plates forming the diaphragms or must be arranged in the inside of the ejection chambers. Particular in the latest

printers, both a high speed and a high printing quality are required so that there is a tendency that the number of the nozzle openings for ejecting ink drops are increased. Piezoelectric elements corresponding to the nozzle openings are machined by dicing or by means of a wire saw and then placed in predetermined positions through an adhesive agent or the like. In the case of a high-density ink-jet recording apparatus having a large number of nozzle openings, if machining is required to provide the piezoelectric elements, there is a limitation from the viewpoints of machining capability, mechanical accuracy and dimensional accuracy.

Further, there have been distortion errors of the piezoelectric elements due to scattering in production of piezoelectric elements per se, and in some cases, there have been occurrence of variations in ink ejection speed from the respective nozzle openings.

Further, electrodes for driving the piezoelectric elements are respectively formed in the piezoelectric elements per se and then the piezoelectric elements are stuck onto a substrate through an adhesive agent. Accordingly, not only the electrodes must be formed individually in the respective piezoelectric elements but the driving efficiency of the ink-jet recording apparatus is lowered because an adhesive agent layer is interposed between the substrate and the piezoelectric elements so that it is made difficult to elongate the lifetime of the ink-jet recording apparatus.

Other than the above system in which the diaphragms are driven by the piezoelectric elements, there is a system in which the ink in the ejection chambers is heated (Japanese Patent Postexam. Publication No. Sho-61-59911). In this system, specifically, the ink in the ejection chambers is heated by a heater so that the pressure in the ejection chambers is increased by the generation of bubbles caused by evaporation of the ink to thereby eject ink drops from the chambers. This heating system has an advantage in that heating resistors can be formed of thin-film resistors of TaSiO<sub>2</sub>, NiWP or the like by sputtering, CVD, evaporating deposition, plating, or the like. The system, however, has a problem in that the lifetime of the head itself is short because the heating resistors are injured by repetition of heating/quenching and shock at the time of the breaking of bubbles in the ink.

US Patent No. 4, 520, 375 discloses an ink-jet device in which a diaphragm is distorted by the application of a pulse voltage from an electric source to a pair of spaced capacitor plates. This device suffers from the drawback that pulsing of the voltage leads to flow back and forth of the ink between the reservoir and the source. The ink is not reliably ejected from the nozzle. Moreover, it is difficult to maintain the necessary high precision gap between the capacitor plates because they are separated by insulating means which is itself subject to flexure.

## SUMMARY OF THE INVENTION

It is therefore an object of the present invention to provide an ink-jet recording apparatus which is small in size, high in density, high in printing speed, high in printing quality, long in life and high in reliability, by employing a driving system using electrostatic force instead of the aforementioned system using piezoelectric elements or heating elements as means for driving diaphragms or vibration plates of ejection chambers.

It is another object of the present invention to provide an ink-jet recording apparatus having a structure which is formed by application of a micro-machining technique and which is suitable for mass-production thereof.

It is a further object of the present invention to provide a method suitable for production of an ink-jet head as a main part of the ink-jet recording apparatus which can attain the foregoing objects.

To attain the foregoing objects, according to the present invention, there is provided an ink-jet recording apparatus comprising an ink-jet head formed by laminating at least three substrates and having a plurality of nozzle openings, a corresponding plurality of ejection chambers respectively communicating with said nozzle openings, from which ink drops are ejected due to the deformation of a diaphragm formed in each of said ejection chambers, and drive means for distorting said diaphragms by electrostatic force obtained by applying pulse voltage to said ink-jet head, said apparatus being characterised by comprising:

a silicon substrate having at least a plurality of first concave portions each constituting a part of the or each ejection chamber, a second concave portion constituting a part of a common ink cavity for supplying ink to said ejection chambers, and a plurality of grooves, each groove being shallower than said first or second concave portion, and serving as an orifice between said ejection chamber and said common ink cavity, and

an upper substrate and a lower substrate bonded to said silicon substrate thereby forming said ejection chamber together with said ink cavity and said orifices, and provided with electrodes opposed to said diaphragms, each of which forms the bottom part of each of said first concave portions, there being a gap provided between the diaphragms and the lower substrate.

The operational principle of the ink-jet recording apparatus is as follows. When a pulse voltage is applied to one electrode, the corresponding diaphragm is attracted and distorted by the negative or positive charge on the surface of the diaphragm and the positive or negative charge on the surface of the electrode corresponding the diaphragm. Then, the volume of the corresponding ejection chamber is reduced by the

restoring force of the diaphragm when the electrode is made off. As a result, the pressure in the ejection chamber is increased instantaneously to thereby eject an ink drop from the corresponding nozzle opening. Because the driving of the diaphragms is controlled by such an electrostatic action, not only this apparatus can be produced by a micro-machining technique but the apparatus can be made small in size, high in density, high in printing speed, high in printing quality, and long in life-time.

According to the present invention, preferably, the ink-jet head has a lamination structure formed by bonding at least three substrates stacked one on another, the ejection chambers respectively having bottom portions used as the diaphragms are provided on an intermediate one of the substrates, and the electrodes are provided on a lowermost one of the substrates so that the electrodes are closely opposite to the diaphragms respectively and correspondingly. Although the respective rear walls of the ejection chambers can be used as the diaphragms, the respective bottom walls of the ejection chambers are used as the diaphragms through a lamination structure formed by bonding at least three substrates in order to make the apparatus thinner. It is preferable that the electrodes are coated with an insulating film not only to protect the electrodes but to prevent the electrodes from short-circuiting with the diaphragms.

To increase the pressure in each of the ejection chambers, the upper and lower walls of the ejection chamber may be constituted by diaphragms. In this case, the electrodes are provided correspondingly to the respective diaphragms so as to synchronously drive the corresponding diaphragms. Accordingly, the driving voltages of the electrodes can be set to lower values.

Further, preferably, each of the diaphragms is shaped to be a rectangle or a square and each of the diaphragms is supported through bellows-like grooves formed on two opposite sides of or on four sides of the rectangle or square, or alternatively, supported by one side of the rectangle or square in the form of a cantilever, so that the quantity of displacement of the diaphragm is made large. In the case of the cantilever type diaphragm, insulating ink is used because there is a possibility that ink becomes into contact with the electrode portion to make the electrodes shorted to make power supply possible.

Further, preferably, a pair of, first and second, electrodes may be provided for each diaphragm in order to increase the electrostatic action more effectively. In this case, the two electrodes may be arranged so that the first electrode is provided inside a vibration chamber just under the diaphragm while the second electrode is provided outside the vibration chamber, or, alternatively, both the two electrodes may be arranged inside the vibration chamber the two electrodes being connected to an oscillation circuit so that electric pulses opposite to each other in polarity are respectively alternately

applied to the two electrodes. Further, by providing a metal electrode opposite to the electrode in the diaphragm, the speed of injection/disappearance of charge can be made high so that it is made possible to realize driving by higher-frequency pulses to thereby obtain a performance of high speed printing.

Further, it is preferable that each vibration chamber is made to communicate with the air through an air passage. The electrodes can be respectively correspondingly disposed in concave portions formed in the substrate.

The nozzle openings may be arranged at equal intervals in an end portion of the intermediate one of the stacked substrates in the form of a so-called edge ink-jet type. Alternatively, the nozzle openings may be arranged at equal intervals in the upper one of the stacked substrates just above the ejection chambers in the form of a so-called face ink-jet type.

The method for producing the ink-jet according to the present invention is set out in claim 14.

Being in the form of a monocrystal, silicon can be subjected to anisotropic etching. For example, the (100) face can be etched regularly in the direction of 55°. The (111) face can be etched in the direction of 90°. By using this property of silicon, it is possible to form the respective important parts, such as nozzle openings, ejection chambers, orifices, an ink cavity, etc., with high accuracy. Finally, the silicon nozzle substrate and the electrode substrate (constituted by a glass or insulating plate which is near in thermal expansion coefficient to silicon) in which electrodes and an insulating film are formed are put on each other and heated at a temperature of 300°C to 500°C. At the same time, a voltage of the order of hundreds of volts is applied between the silicon side as an anode and the electrode substrate side as a cathode to stick the substrate to each other through anodic bonding. Thus, an ink-jet head being high in airtightness can be produced.

#### DESCRIPTION OF THE PREFERRED EMBODIMENTS

Embodiments of the present invention will be described hereunder with reference to the drawings.

##### Embodiment 1

Fig. 1 is a partly exploded perspective view partly in section, of an ink-jet recording apparatus according to a first embodiment of the present invention. The illustrated embodiment relates to an edge ink-jet type apparatus in which ink drops are ejected from nozzle openings formed in an end portion of a substrate. Fig. 2 is a sectional side view of the whole apparatus after assembly. Fig. 3 is a view taken on line A - A of Fig. 2.

As shown in the drawings an ink-jet head 12 as a main portion of an ink-jet recording apparatus 10 has a lamination structure in which three substrate 1, 2 and 3 are stuck to one another as will be described hereunder.

An intermediate substrate 2 such as a silicon substrate has: a plurality of nozzle grooves 21 arranged at equal intervals on a surface of the substrate and extending in parallel to each other from an end thereof to form nozzle openings; concave portions 22 respectively communicated with the nozzle grooves 21 to form ejection chambers 6 respectively having bottom walls serving as diaphragms 5; fine grooves 23 respectively provided in the rear of the concave portions 22 and serving as ink inlets to form orifices 7; and a concave

portion 24 to form a common ink cavity 8 for supplying in to the respective ejection chambers 6. Further, concave portions 25 are respectively provided under the diaphragms 5 to form vibration chambers 9 so as to mount electrodes as will be described later. The nozzle grooves 21 are arranged at intervals of the pitch of about 2mm. The width of each nozzle groove 21 is selected to be about 40  $\mu\text{m}$ .

For example, the upper substrate 1 stuck onto the upper surface of the intermediate substrate 2 is made by glass or resin. The nozzle openings 4, the ejection chambers 6, the orifices 7 and the ink cavity 8 are formed by bonding the upper substrate 1 on the intermediate substrate 2. An ink supply port 14 communicated with the ink cavity 8 is formed in the upper substrate 1. The ink supply port 14 is connected to an ink tank not shown, through a connection pipe 14 and a tube 17.

For Example, the lower substrate 3 to be bonded on the lower surface of the intermediate substrate 2 is an insulating substrate consisting of, for example glass. The vibration chambers 9 are formed by bonding the lower substrate 3 on the intermediate substrate 2. At the same time, electrodes 31 are formed on a surface of the lower substrate 3 and in positions corresponding to the respective diaphragms 5. Each of the electrodes 31 has a lead portion 32 and a terminal portion 33. The electrodes 31 and the lead portions 32 except the terminal portions 33 are covered with an insulating film 34. The terminal portions 33 are respectively correspondingly bonded to lead wires 35.

The substrates 1, 2 and 3 are assembled to constitute an ink-jet head 12 as shown in Fig. 2. Further, oscillation circuits 26 are respectively correspondingly connected between the terminal portions 33 of the electrodes 31 and the intermediate substrate 2 to thereby constitute the ink-jet recording apparatus 10 having a lamination structure according to the present invention. Ink 11 is supplied from the ink tank (not shown) to the inside of the intermediate substrate 2 through the ink supply port 14, so that the ink cavity 8, the ejection chambers 6 and the like are filled with the ink. The distance  $c$  between the electrode 31 and the corresponding diaphragm 5 is kept to be about 1  $\mu\text{m}$ . In Fig. 2, the reference numeral 13 designates an ink drop ejected from the nozzle opening 4, and 15 designates recording paper. The ink used is prepared by dissolving/dispersing a surface active agent such as ethylene glycol and a dye (or a pigment) into a main solvent such as water, alcohol, toluene, etc. Alternatively, hot-melt ink may be used if a heater or the like is provided in this apparatus.

In the following, the operation of this embodiment is described. For example, a positive pulse voltage generated by one of the oscillation circuits 26 is applied to the corresponding electrode 31. When the surface of the electrode 31 is charged with electricity to a positive potential, the lower surface of the corresponding diaphragm 5 is charged with electricity to a negative potential. Accordingly, the diaphragm 5 is distorted downward by the action of the electrostatic attraction. When the electrode 31 is then made off, the diaphragm 5 is restored. Accordingly, the pressure in the ejection chamber 6 increases rapidly, so that the ink drop 13 is ejected from the nozzle opening 4 onto the recording paper 15. Further, the ink 11 is supplied from the ink cavity 8 to the ejection chamber 6 through the orifice 7 by the downward distortion of the diaphragm 5. As the oscillation circuit 26, a circuit for alternately generating a zero voltage and a positive voltage, an AC electric source, or the like, may be used. Recording can be made by controlling the electric pulses to be applied to the electrodes 31 of the respective nozzle openings 4.

Here, the quantity of displacement, the driving voltage and the quantity of ejection of the diaphragm 5 are calculated in the case where the diaphragm 5 is driven as described above.

The diaphragm 5 is shaped like a rectangle with short side length  $2a$  and long side length  $b$ . The four sides of the rectangle are supported by surrounding walls. When the aspect ratio ( $b/2a$ ) is large, the coefficient approaches to 0.5, and the quantity of displacement of the thin plate (diaphragm) subjected to pressure  $P$  can be expressed by the following formula because the quantity of displacement depends on  $a$ .

$$w = 0.5 \times Pa^4 / Eh^3 \quad (1)$$

In the formula,

- $w$ : the quantity of displacement (m)
- $p$ : pressure ( $\text{N/m}^2$ )
- $a$ : a half length(m) of the short side
- $h$ : the thickness  $k$ (m) of the plate (diaphragm)
- $E$ : Young's modulus ( $\text{N/m}^2$ , silicon  $11 \times 10^{10} \text{ N/m}^2$ )

The pressure of attraction by electrostatic force can be expressed by the following formula.

$$P = 1/2 \times \epsilon \times (V/t)^2$$

In the formula,

- $\epsilon$ : the dielectric constant (F/m, the dielectric constant in vacuum:  $8.8 \times 10^{-12} \text{ F/m}$ )
- $V$ : the voltage (V)
- $t$ : the distance (m) between the diaphragm and the electrode

Accordingly, the driving voltage  $V$  required for acquiring necessary ejection pressure can be expressed by the following formula.

$$V = t(2P/\epsilon)^{1/2} \quad (2)$$

In the following, the volume of a semicylindrical

shape as shown in Fig. 4(B) is calculated to thereby calculate the quantity of ejection.

The following formula can be obtained because the equation  $\Delta w = 4/3 \times abw$  is valid.

$$w = 3/4 \times \Delta w / ab \quad (3)$$

When the formula (3) is substituted into the equation  $P = 2w \times Eh^3/a^4$  obtained by rearranging the formula (1), the following formula (4) can be obtained.

$$P = 3/2 \times \Delta Eh^3/a^5 b \quad (4)$$

When the formula (4) is substituted into the formula (2), the following formula can be obtained.

$$V = t \times (3Eh^3 \Delta w / \epsilon b)^{1/2} \times (1/a^5)^{1/2} \quad (5)$$

That is, the driving voltage required for acquiring the quantity of ejection of ink is expressed by the formula (5).

The allowable region of ink ejection as shown in Fig. 5A can be calculated on the basis of the formulae (2) and (5). Fig. 5A shows the relationship between the short side length  $2a$ (mm) and the driving voltage (V) in the case where the long side length  $b$  of the silicon diaphragm, the thickness  $h$  thereof and the distance  $c$  between the diaphragm and the electrode are selected to be 5mm, 80  $\mu$ m and 1  $\mu$ m respectively. The ejection allowable region 30 is shown by the oblique lines in Fig. 5A when the jet (ejection) pressure  $P$  is 0.3 atm.

Although it is more advantageous for the diaphragm to make the size of the diaphragm larger, the appropriate width of the nozzle in the direction of the pitch is within a range of from about 0.5mm to about 4.0mm in order to make the nozzle small in size and high in density.

The length of the diaphragm is determined according to the formula (4) on the basis of the quantity of ejection of ink as a target, the Young's modulus of the silicon substrate, the ejection pressure thereof and the thickness thereof.

When the width is selected to be about 2mm, it is necessary to select the thickness of the diaphragm to be about 50  $\mu$ m or more on the consideration of the ejection rate. If the diaphragm is extremely thicker than the above value, the driving voltage increases abnormally as obvious from the formula (5). If the diaphragm is too thin, the ink-jet ejection frequency cannot be obtained. That is, a large lag occurs in the frequency of the diaphragm relative to the applied pulses for ink jetting.

After the ink-jet head 12 in this embodiment was assembled into a printer, ink drops were flown in the rate of 7m/sec by applying a voltage of 150 V with 5KHz. When printing was tried at a rate of 300 dpi, a good result of printing was obtained.

Though not shown, the rear wall of the ejection

chamber may be used as a diaphragm. The head itself, however, can be more thinned by using the bottom wall of the ejection chamber 6 as a diaphragm as shown in this embodiment.

## Embodiment 2

Fig. 6 is a sectional view of a second embodiment of the present invention showing an edge ink-jet type apparatus similarly to the first embodiment.

In this embodiment, the upper and lower walls of the ejection chamber 6 are used as diaphragms 5a and 5b. Therefore, two intermediate substrates 2a and 2b are used and stuck to each other through the ejection chamber 6. The diaphragms 5a and 5b and vibration chambers 9a and 9b are respectively formed in the substrates 2a and 2b. The substrates 2a and 2b are arranged symmetrically with respect to a horizontal plane so that the diaphragms 5a and 5b form the upper and lower walls of the ejection chamber 6. The nozzle opening 4 is formed in an edge junction surface between the two substrates 2a and 2b. Further, electrodes 31a and 31b are respectively provided on the lower surface of the upper substrate 1 and on the upper surface of the lower substrate 3 and respectively mounted into the vibration chambers 9a and 9b. Oscillation circuits 26a and 26b connected respectively between the electrode 31a and the intermediate substrate 2a and between the electrode 31b and the intermediate substrate 2b.

In this embodiment, the diaphragms 5a and 5b can be driven by a lower voltage because an ink drop 13 can be ejected from the nozzle opening 4 by symmetrically vibrating the upper and lower diaphragms 5a and 5b of the ejection chamber 6 through the electrodes 31a and 31b. The pressure in the ejection chamber 6 is increased by the diaphragms 5a and 5b vibrating symmetrically with respect to a horizontal plane, so that the printing speed is improved.

## Embodiment 3

The following embodiments show face ink-jet type apparatus in which ink drops are ejected from nozzle openings, provided in a surface of a substrate. The object of the embodiments is to drive diaphragms by a lower voltage. The embodiments can be applied to the aforementioned edge ink jet type apparatus.

Fig. 7 shows a third embodiment of the present invention in which each circular nozzle opening 4 is formed in an upper substrate 1 just above an ejection chamber 6. The bottom wall of the ejection chamber 6 is used as a diaphragm 5. The diaphragm 5 is formed on an intermediate substrate 2. Further, an electrode 31 is formed on a lower substrate 3 and in a vibration chamber 9 under the diaphragm 5. An ink supply port 14 is provided in the lower substrate 3.

In this embodiment, an ink drop 13 is ejected from

the nozzle opening 4 provided in the upper substrate, through the vibration of the diaphragm 5. Accordingly, a large number of nozzle openings 4 can be provided in one head, so that high-density recording can be made.

#### Embodiment 4

In this embodiment, as shown in Figs. 8, 9A and 9B, each diaphragm 5 is supported by at least one bellows-shaped groove 27 provided on the two opposite sides (see Fig. 9A) or four sides (see Fig. 9B) of a rectangular diaphragm 5 to thereby make it possible to increase the quantity of displacement of the diaphragm 5. Ink in the ejection chamber 6 can be pressed by a surface of the diaphragm 5 perpendicular to the direction of ejection of ink, so that the ink drop 13 can be flown straight.

#### Embodiment 5

In this embodiment, the rectangular diaphragm 5 is formed as a cantilever type diaphragm supported by one short side thereof. By making the diaphragm 5 be of the cantilever type, the quantity of displacement of the diaphragm 5 can be increased without making the driving voltage high. Because the ejection chamber 6 becomes communicated with the vibration chamber, however, it is necessary that insulating ink is used as the ink 11 to secure electrical insulation of the ink from the electrode 31.

#### Embodiment 6

In this embodiment, two electrodes 31c and 31d are provided for each diaphragm 5 as shown in Fig. 11 so that the two electrodes 31c and 31d drive the diaphragm 5.

In this embodiment, the first electrode 31c is arranged inside a vibration chamber 9, and, on the other hand, the second electrode 31d is arranged outside the vibration chamber 9 and under an intermediate substrate 2. An oscillation circuit 26 is connected between the two electrodes 31c and 31d, and ON-OFF of the voltage application to the electrodes 31c and 31d is repeated to thereby drive the diaphragm 5.

According to this structure, the driving portion is electrically independent because the silicon substrate 2 is not used as a common electrode unlike the previous embodiment. Accordingly, ejection of ink from an unexpected nozzle opening can be prevented when a nozzle head adjacent thereto is driven. Further, in the case of using a high resistance silicon substrate, or in the case where a high resistance layer is formed, though not shown in Fig. 11, on the surface of the silicon substrate 2, pulse voltages opposite to each other in polarity may be alternately applied to the two electrodes 31c and 31d to thereby drive the diaphragm 5. In this case, not only electrostatic attraction as described above but repulsion

act on the diaphragm 5. Accordingly, ejection pressure can be increased by a lower voltage.

#### Embodiment 7

In this embodiment, as shown in Fig. 12, both of the electrode 31c and 31d are arranged inside the vibration chamber 9 so that the diaphragm 5 is driven by surface polarization of silicon. That is, in the same manner as in the embodiment of Fig. 11, ON-OFF of the voltage application to the electrodes 31c and 31d is repeated to thereby drive the diaphragm 5. Further, in the same manner as in the Embodiment 6, in the case of using a high resistance silicon substrate, or in the case where a high resistance layer is formed, though not shown in Fig. 12, on the surface of the silicon substrate 2, pulse voltages opposite to each other in polarity may be alternately applied to the two electrodes 31c and 31d to thereby drive the diaphragm 5. This embodiment is however different from the embodiment of Fig. 11 in that there is no projection of the electrodes between the intermediate substrate 2 and the lower substrate 3. Accordingly, in this embodiment, the two substrates can be bonded with each other easily.

#### Embodiment 8

In this embodiment, as shown in Fig. 13, a metal electrode 31e is provided on the lower surface of the diaphragm 5 so as to be opposite to the electrode 31. Because electric charge is not supplied to the diaphragm 5 through the silicon substrate 2 but supplied to the metal electrode 31e formed on the diaphragm 5 through metal patterned lines, the charge supply rate can be increased to thereby make high-frequency driving possible.

#### Embodiment 9

In this embodiment, as shown in Fig. 14, an air vent or passage 28 is provided to well vent air in the vibration chamber 9. Because the diaphragm 5 cannot be vibrated easily when the vibration chamber 9 just under the diaphragm 5 is high in air tightness, the air vent 28 is provided between the intermediate substrate 2 and the lower substrate 3 in order to release the pressure in the vibration chamber 9.

#### Embodiment 10

In this embodiment, as shown in Fig. 15, the electrode 31 for driving the diaphragm 5 is formed in a concave portion 29 provided in the lower substrate 3. The short circuit of electrodes caused by the vibration of the diaphragm 5 can be prevented without providing any insulating film for the electrode 31.

In the following, an embodiment of a method for producing the aforementioned ink-jet head 12 is

described. Description will be made with respect to the structure of Fig. 1 as the central subject. The nozzle grooves 4, the diaphragm 5, the ejection chambers 6, the orifices 7, the ink cavity 8, the vibration chambers 9 etc., are formed in the intermediate substrate (which is also called "nozzle substrate") 2 through the following steps.

#### (1) Silicon Thermally Oxidizing Step (Diagram of Fig. 16A)

A silicon monocrystal substrate 2A of face orientation (100) was used. Both the opposite surfaces of the substrate 2A were polished to a thickness of 280  $\mu\text{m}$ . Silicon was thermally oxidized by heating the Si substrate 2A in the air at 1100°C for an hour to thereby form a 1  $\mu\text{m}$ -thick oxide film 2B of  $\text{SiO}_2$  on the whole surface thereof.

#### (2) Patterning Step (Diagram of Fig. 16B)

A resist pattern 2C was formed through the steps of: successively coating the two surfaces of the Si substrate 2A with a resist (OMR-83™ made by TOKYO OHKA) by a spin coating method to form a resist film having a thickness of about 1  $\mu\text{m}$ ; and making the resist film subject to exposure and development to form a predetermined pattern. The pattern determining the form of the diaphragm 5 was a rectangle with a width of 1mm and with a length of 5mm. In the embodiment of Fig. 7, the form of the diaphragm was a square having an each side length of 5mm.

Then, the  $\text{SiO}_2$  film 2B was etched under the following etching condition as shown in the drawing. While a mixture solution containing six parts by volume of 40 wt% ammonium fluoride solution to one of 50 wt% hydrofluoric acid was kept at 20°C, the aforementioned substrate was immersed in the mixture solution for 10 minutes.

#### (3) Etching Step (Diagram of Fig. 16)

The resist 2C was separated under the following etching condition. While a mixture solution containing four parts by volume of 98 wt% sulfuric acid to one of 30 wt% hydrogen peroxide was heated to 90°C or higher, the substrate was immersed in the mixture solution for 20 minutes to separate the resist 2C. Then, the Si substrate 2A was immersed in a solution of 20 wt% KOH at 80°C for a minute to perform etching by a depth of 1  $\mu\text{m}$ . A concave portion 25 constituting a vibration chamber 9 was formed by the etching.

#### (4) Opposite Surface Patterning Step (Diagram of Fig 16D)

The  $\text{SiO}_2$  film remaining in the Si substrate 2A was completely etched in the same condition as in the step

(2). Then, a 1  $\mu\text{m}$ -thick  $\text{SiO}_2$  film was formed over the whole surface of the Si substrate 2A by thermal oxidation through the same process as shown in the steps (1) and (2). Then, the  $\text{SiO}_2$  film 2B on the opposite surface (the lower surface in the drawing) of the Si substrate 2A was etched into a predetermined pattern through a photolithographic process. The pattern determined the form of the ejection chamber 6 and the form of the ink cavity 8.

#### (5) Etching Step (Diagram of Fig. 16E)

The Si substrate 2A was etched by using the  $\text{SiO}_2$  film as a resist through the same process in the step (3) to thereby form concave portions 22 and 24 for the ejection chamber 6 and the ink cavity 8. At the same time, a groove 21 for the nozzle opening 4 and the groove 23 of an orifice 7 were formed. The thickness of the diaphragm 5 was 100  $\mu\text{m}$ .

In respect to the nozzle groove and the orifice groove, the etching rate in the KOH solution became very slow when the (111) face of the Si substrate appeared in the direction of etching. Accordingly, the etching progressed no more, so that the etching was stopped with the shallow depth. When, for example, the width of the nozzle groove is 40  $\mu\text{m}$ , the etching is stopped with the depth of about 28  $\mu\text{m}$ . In the case of the ejection chamber or the ink cavity, it can be formed sufficiently deeply because the width is sufficiently larger than the etching depth. That is, portions different in depth can be formed at once by an etching process.

#### (6) $\text{SiO}_2$ Film Removing Step (Diagram of Fig. 16F)

Finally, a nozzle substrate having parts 21, 22, 23, 24, 25 and 5, or in other words, an intermediate substrate 2, was prepared by removing the remaining  $\text{SiO}_2$  film by etching.

In the embodiment in Fig. 7, an intermediate substrate having the aforementioned parts 22, 23, 24, 25 and 5 except the nozzle grooves 21 and a nozzle substrate (upper substrate 1) having nozzle openings 4 with the diameter 50  $\mu\text{m}$  on a 280  $\mu\text{m}$ -thick Si substrate were prepared in the same process as described above.

In the following, a method for forming an electrode substrate (lower substrate 3) is described with reference to Fig. 17.

#### (1) Metal Film Forming Step (Diagram of Fig. 17A)

A 1000 Å-thick Ni film 3B was formed on a surface of a 0.7 mm-thick Pyrex™ glass substrate 3A by a sputtering method.

#### (2) Electrode Forming Step (Diagram of Fig. 17B)

The Ni film 3B was formed into a predetermined pattern by a photolithographic etching technique. Thus,

the electrodes 31, the lead portions 32 and the terminal portions 33 were formed.

### (3) Insulating Film Forming Step (Diagram of Fig. 17C)

Finally, the electrodes 31 and the lead portions 32 (see Fig. 1) except the terminal portions 33 were completely coated with an SiO<sub>2</sub> film as an insulating film by a mask sputtering method to form a film thickness of about 1 μm to thereby prepare the electrode substrate 3.

The nozzle substrate 2 and the electrode substrate 3 prepared as described above were stuck to each other through anodic bonding. That is after the Si substrate 2 and the glass substrate 3 were put on each other, the substrates were put on a hot plate. While the substrates were heated at 300°C, a DC voltage of 500 V was applied to the substrates for 5 minutes with the Si substrate side used as an anode and with the glass substrate side used as a cathode to thereby stick the substrates to each other. Then, the glass substrate (upper substrate 1) having the ink supply port 14 formed therein was stuck onto the Si substrate 2 through the same anodic treatment.

In the embodiment of Fig. 7, the nozzle substrate 1 and the Si substrate 2 were stuck on each other through thermal compression.

The ink-jet heads 12 respectively shown in Figs. 2 and 7 were produced through the aforementioned process.

### Claims

1. An ink-jet recording apparatus comprising an ink-jet head formed by laminating at least three substrates (1, 2, 3) and having a plurality of nozzle openings (4), a corresponding plurality of ejection chambers (6) respectively communicating with said nozzle openings (4), from which ink drops are ejected due to the deformation of a diaphragm (5) formed in each of said ejection chambers, and drive means (26) for distorting said diaphragms (5) by electrostatic force obtained by applying pulse voltage to said ink-jet head, said apparatus being characterised by comprising:

a silicon substrate (2, 2a, 2b) having at least a plurality of first concave portions (22) each constituting a part of the or each ejection chamber (6), a second concave portion (24) constituting a part of a common ink cavity (8) for supplying ink to said ejection chambers, and a plurality of grooves (23), each groove being shallower than said first or second concave portion, and serving as an orifice (7) between said ejection chamber and said common ink cavity, and an upper substrate (1) and a lower substrate (3) bonded to said silicon substrate thereby

forming said ejection chamber together with said ink cavity and said orifices, and provided with electrodes (31, 31a, 31b) opposed to said diaphragms (5, 5a, 5b), each of which forms the bottom part of each of said first concave portions, there being a gap (c) provided between the diaphragms (5, 5a, 5b) and the lower substrate (3).

2. An ink-jet recording apparatus as claimed in claim 1, characterised in that at least one of said upper or lower substrates is of a glass type.
3. An ink-jet recording apparatus as claimed in either claim 1 or claim 2, characterised in that said electrodes (31) are covered with an insulating film (34).
4. An ink-jet recording apparatus as claimed in any one of the preceding claims, characterised in that said silicon substrate consists of a first and a second silicon substrate (2a, 2b) attached to each other to form said ejection chamber, and further characterised in that upper and lower substrates are formed with electrodes (31a, 31b) opposed to diaphragms (5a, 5b) with a gap therebetween.
5. An ink-jet recording apparatus as claimed in any one of the preceding claims, characterised in that each of said diaphragms (5) is shaped to be a rectangle or a square and is supported through bellows-like grooves (27) formed on two opposite sides of or on four sides of said rectangle or square.
6. An ink-jet recording apparatus as claimed in any one of Claims 1 to 4, characterised in that each of said diaphragms (5) is shaped to be a rectangle or a square, one side of which is supported in the form of a cantilever, and insulating ink is used as said ink.
7. An ink-jet recording apparatus as claimed in any one of the preceding claims, characterised in that said electrodes (31) are provided so that a pair of first and second electrodes are formed for each of said diaphragms (5), said first electrode (31) being disposed inside a vibration chamber (9) provided just under said diaphragm (5), said second electrode (33) being disposed outside said vibration chamber (9), and in that an oscillation circuit is provided so as to apply electric pulses opposite in polarity to each other alternately to said two electrodes (31, 33).
8. An ink-jet recording apparatus as claimed in any one of Claims 1 to 6, characterised in that two electrodes (31) are disposed within a vibration chamber (9) provided adjacent each diaphragm (5).

9. An ink-jet recording apparatus as claimed in any one of Claims 1 to 6, characterised in that metal electrodes are respectively correspondingly provided in said diaphragms so that said metal electrodes are opposite to said electrodes (31).

10. An ink-jet recording apparatus as claimed in either claim 7 or claim 8, characterised in that said vibration chambers (9) communicate with the air through air passages.

11. An ink-jet recording apparatus as claimed in any one of claims 1, 2, 3, 4, 7, 8 or 9 characterised in that said electrodes (31, 31a, 31b) are respectively provided in concave portions (25, 29) of said silicon or lower substrates (2, 3).

12. An ink-jet recording apparatus as claimed in either claim 1 or claim 2, characterised in that said nozzles (4) are arranged at equal intervals in an end portion of said silicon substrate (2).

13. An ink-jet recording apparatus as claimed in any one of claims 1 to 10, characterised in that said nozzle openings (4) are arranged at equal intervals in the uppermost substrate (1), each above a respective ejection chamber (6).

14. A method for producing an ink-jet head for an ink-jet recording apparatus, the method comprising the steps of:

anisotropically etching a silicon substrate (2) on a first surface thereof to form a plurality of concave portions (22, 24), the rims of which delineate a plurality of ejection chambers (6) having bottom walls serving as diaphragms (5), a common cavity (8) and grooves (23) serving as ink inlets (7), the arrangement being such that a plurality of said grooves (23) communicates between an end of each ejection chamber (6) and the common cavity (8); bonding a first insulating substrate to said first surface of the silicon substrate (2), and forming electrodes (31) on a first surface of a second insulating substrate (3), and bonding said second insulating substrate (3) to the surface of the silicon substrate (2) opposite said first surface such that said electrodes (31) face said diaphragms (5) with a gap (c) therebetween.

15. A method as claimed in claim 14 comprising the further step of anisotropically etching the silicon substrate (2) on the surface thereof opposite said first surface in register with said ejection chambers (6) to form vibration chambers (9) beneath said diaphragms (5).

16. A method as claimed in claim 14 or claim 15 wherein said second insulating substrate (3) has a concave portion (29) on which said electrodes (31) are formed.

17. A method as claimed in any one of claims 14 to 16 comprising the further step of forming an insulating layer (34) on said electrodes (31).

18. A method as claimed in any one of claims 14 to 17 wherein said step of anisotropically etching said first surface of said silicon substrate further comprises the formation of nozzle grooves (21) arranged at equal intervals on said first surface in communication with said concave portions (22) and intersecting one edge of said silicon substrate (2) at nozzle openings (4).

19. A method as claimed in any one of claims 14 to 17 wherein nozzle openings (4) are arranged at equal intervals in said first insulating substrate (1), each nozzle opening (4) being located above a respective ejection chamber (6).

20. A method as claimed in any one of claims 14 to 17 wherein said second insulating substrate (3) is bonded to the surface of the silicon substrate (2) opposite said first surface by anodic bonding.

#### Patentansprüche

1. Tintenstrahlzeichnungsgerät mit einem Tintenstrahlkopf, der durch Laminieren von zumindest drei Substraten (1, 2, 3) ausgebildet ist und eine Vielzahl von Düsenöffnungen (4) aufweist, mit einer entsprechenden Vielzahl von Ausstoßkammern (6), die jeweils mit den entsprechenden Düsenöffnungen (4) kommunizieren, aus denen Tintentropfen aufgrund der Deformation einer Membran (5) ausgestoßen werden, die in jeder dieser Ausstoßkammern ausgebildet ist, und mit Antriebseinrichtungen (26) zum Auslenken dieser Membranen (5) mittels einer elektrostatischen Kraft, die erhalten wird durch Anlegen einer Impulsspannung an diesen Tintenstrahlkopf, wobei dieses Gerät dadurch gekennzeichnet ist, daß es enthält:

ein Silikonsubstrat (2, 2a, 2b) mit zumindest einer Vielzahl von ersten konkaven Abschnitten (22), die jeweils einen Teil von der oder von jeder Ausstoßkammer (6) bilden, einen zweiten konkaven Abschnitt (24), der einen Teil eines gemeinsamen Tintenohlraumes (8) bildet für die Zuführung von Tinte zu diesen Ausstoßkammern, und eine Vielzahl von Rinnen (23), wobei jede Rinne seichter ist als dieser erste oder zweite konkave Abschnitt und als eine Öffnung (7) zwischen dieser Ausstoßkammer

und diesem gemeinsamen Tintenhohlraum dient, und

ein oberes Substrat (1) sowie ein unteres Substrat (3), die mit diesem Silikonsubstrat verbunden sind, wodurch diese Ausstoßkammer zusammen mit diesem Tintenhohlraum und diesen Öffnungen ausgebildet ist, und mit Elektroden (31, 31a, 31b) versehen sind, die diesen Membranen (5, 5a, 5b) gegenüberliegen, wovon jede den Bodenabschnitt von jedem dieser ersten konkaven Abschnitte bildet, wobei zwischen den Membranen (5, 5a, 5b) und dem unteren Substrat (3) eine Lücke (c) ausgebildet ist.

2. Tintenstrahlauzeichnungsgerät nach Anspruch 1, **dadurch gekennzeichnet**, daß zumindest eines dieser oberen oder unteren Substrate ein Substrat eines Glas-Typs ist.
3. Tintenstrahlauzeichnungsgerät entweder nach Anspruch 1 oder nach Anspruch 2, **dadurch gekennzeichnet**, daß diese Elektroden (31) mit einem Isolationsfilm (4) abgedeckt sind.
4. Tintenstrahlauzeichnungsgerät nach einem der vorstehenden Ansprüche, **dadurch gekennzeichnet**, daß dieses Silikonsubstrat aus einem ersten und aus einem zweiten Silikonsubstrat (2a, 2b) besteht, die miteinander verbunden sind, um diese Ausstoßkammer auszubilden, und des weiteren **dadurch gekennzeichnet**, daß die oberen und unteren Substrate mit Elektroden (31a, 31b) ausgeformt sind, die den Membranen (5a, 5b) gegenüberliegen, wobei eine Lücke dazwischen ausgebildet ist.
5. Tintenstrahlauzeichnungsgerät nach einem der vorstehenden Ansprüche, **dadurch gekennzeichnet**, daß jede dieser Membranen (5) so ausgeformt ist, daß sie ein Rechteck oder ein Quadrat darstellt und abgestützt ist durch faltenbalgähnliche Rinnen (27), die an zwei einander entgegengesetzten Seiten oder an vier Seiten dieses Rechteckes oder dieses Quadrates ausgeformt sind.
6. Tintenstrahlauzeichnungsgerät nach einem der Ansprüche 1 bis 4, **dadurch gekennzeichnet**, daß jede dieser Membranen (5) so ausgeformt ist, daß sie ein Rechteck oder ein Quadrat bildet, wobei eine Seite von diesen abgestützt ist wie ein Ausleger und wobei isolierende Tinte verwendet wird als diese Tinte.
7. Tintenstrahlauzeichnungsgerät nach einem der vorstehenden Ansprüche, **dadurch gekennzeichnet**, daß diese Elektroden (31) derart angeordnet sind, daß ein Paar von ersten und zweiten Elektroden für jede dieser Membranen (5) ausgebildet ist,

wobei diese erste Elektrode (31) innerhalb einer Vibrationskammer (9) angeordnet ist, die unmittelbar unter dieser Membrane (5) vorgesehen ist, wobei diese zweite Elektrode (33) außerhalb dieser Vibrationskammer (9) angeordnet ist, sowie **dadurch gekennzeichnet** ist, daß ein Schwingkreis vorhanden ist, um elektrische Impulse entgegengesetzter Polarität alternierend an diese zwei Elektroden (31, 33) anzulegen.

8. Tintenstrahlauzeichnungsgerät nach einem der Ansprüche 1 bis 6, **dadurch gekennzeichnet**, daß zwei Elektroden (31) innerhalb einer Vibrationskammer (9) an jeder Membrane (5) angrenzend angeordnet sind.
9. Tintenstrahlauzeichnungsgerät nach einem der Ansprüche 1 bis 6, **dadurch gekennzeichnet**, daß Metallelektroden entsprechend korrespondierend in diesen Membranen derart angeordnet sind, daß diese Metallelektroden diesen Elektroden (31) gegenüberliegen.
10. Tintenstrahlauzeichnungsgerät entweder nach Anspruch 7 oder nach Anspruch 8, **dadurch gekennzeichnet**, daß diese Vibrationskammern mit der Umgebungsluft über Luftkanäle kommunizieren.
11. Tintenstrahlauzeichnungsgerät nach einem der Ansprüche 1, 2, 3, 4, 7, 8 oder 9, **dadurch gekennzeichnet**, daß die Elektroden (31, 31a, 31b) entsprechend in den konkaven Abschnitten (25, 29) der Silikon- oder unteren Substrate (2, 3) angeordnet sind.
12. Tintenstrahlauzeichnungsgerät entweder nach Anspruch 1 oder nach Anspruch 2, **dadurch gekennzeichnet**, daß diese Düsen (4) mit gleichen Intervallen in einem Endabschnitt von diesem Silikonsubstrat (2) angeordnet sind.
13. Tintenstrahlauzeichnungsgerät nach einem der Ansprüche 1 bis 10, **dadurch gekennzeichnet**, daß die Düsenöffnungen (4) mit gleichen Intervallen in dem obersten Substrat (1) angeordnet sind, und zwar jede oberhalb einer entsprechenden Ausstoßkammer (6).
14. Verfahren zur Herstellung eines Tintenstrahlkopfes für ein Tintenstrahlauzeichnungsgerät, wobei das Verfahren die Schritte aufweist:

anisotropes Ätzen eines Silikonsubstrates (2) auf einer ersten Oberfläche davon, um eine Vielzahl von konkaven Abschnitten (22, 24) auszubilden, wobei deren Stege eine Vielzahl von Ausstoßkammern (6), die als Membranen

- (5) dienende Bodenwandungen aufweisen, einen gemeinsamen Hohlraum (8) sowie Rinnen (23), die als Tinteneinlässe (7) dienen, bestimmen, wobei die Anordnung derart ausgestaltet ist, daß an der Vielzahl von diesen Rinnen (23) zwischen einem Ende von jeder Ausstoßkammer (6) und dem gemeinsamen Hohlraum (8) kommunizieren;
- Befestigen eines ersten isolierenden Substrates an dieser ersten Oberfläche des Silikonsubstrates (2), und
- Ausbilden von Elektroden (1) auf einer ersten Oberfläche eines zweiten isolierenden Substrates (3) sowie Verbinden dieses zweiten isolierenden Substrates (3) mit der Oberfläche des Silikonsubstrates (2), und zwar derart der ersten Oberfläche gegenüberliegend, daß diese Elektroden (31) zu den Membranen (5) weisen, wobei eine Lücke (c) dazwischen vorhanden ist.
15. Verfahren nach Anspruch 14, gekennzeichnet durch den weiteren Schritt des anisotropischen Ätzens des Silikonsubstrates (2) auf seiner Oberfläche, und zwar entgegengesetzt dieser ersten Oberfläche sowie fluchtend mit diesen Ausstoßkammern (6), um Vibrationskammern (9) unterhalb dieser Membranen (5) auszuformen.
16. Verfahren nach Anspruch 14 oder nach Anspruch 15, dadurch gekennzeichnet, daß dieses zweite isolierende Substrat (3) einen konkaven Abschnitt (29) aufweist, auf dem diese Elektroden (31) ausgeformt sind.
17. Verfahren nach einem der Ansprüche 14 bis 16, gekennzeichnet durch den weiteren Schritt des Ausbildens einer isolierenden Schicht (34) auf diesen Elektroden (31).
18. Verfahren nach einem der Ansprüche 14 bis 17, dadurch gekennzeichnet, daß der Schritt des anisotropischen Ätzens dieser ersten Oberfläche auf diesem Silikonsubstrat des weiteren umfaßt das Ausbilden von Düsenrinnen (21), die mit gleichen Intervallen auf dieser ersten Oberfläche ausgebildet sind und mit diesen konkaven Abschnitten (22) in Verbindung stehen sowie eine Kante dieses Silikonsubstrates (2) bei den Düsenöffnungen (4) kreuzen.
19. Verfahren nach einem der Ansprüche 14 bis 17, dadurch gekennzeichnet, daß die Düsenöffnungen (4) mit gleichen Intervallen auf diesem ersten isolierenden Substrat (1) angeordnet sind, wobei jede Düsenöffnung (4) oberhalb einer entsprechenden Ausstoßkammer (6) angeordnet ist.

20. Verfahren nach einem der Ansprüche 14 bis 17, dadurch gekennzeichnet, daß dieses zweite isolierende Substrat (3) mit der Oberfläche des Silikonsubstrates (2) der ersten Oberfläche gegenüberliegend mittels eines anodischen Verbindungsprozesses verbunden ist.

#### Revendications

1. Dispositif d'enregistrement à jet d'encre comprenant une tête à jet d'encre formée en stratifiant au moins trois substrats (1, 2, 3) et ayant une pluralité d'ouvertures de buses (4), une pluralité correspondante de chambres d'éjection (6) respectivement en communication avec lesdites ouvertures de buses (4), par où les gouttes d'encre sont éjectées sous l'effet de la déformation d'un diaphragme (5) formé dans chacune desdites chambres d'éjection, et des moyens d'entraînement (26) servant à déformer lesdits diaphragmes (5) par une force électrostatique obtenue en appliquant une tension pulsée à ladite tête à jet d'encre, ledit dispositif étant caractérisé en ce qu'il comprend :
- un substrat en silicium (2, 2a, 2b) ayant au moins une pluralité de premières portions concaves (22) dont chacune constitue une partie de la ou de chaque chambre d'éjection (6), une deuxième portion concave (24) constituant une partie d'une cavité d'encre commune (8) servant à acheminer l'encre auxdites chambres d'éjection, et une pluralité de rainures (23), chaque rainure étant moins profonde que ladite première ou deuxième portion concave, et jouant le rôle d'un orifice (7) entre ladite chambre d'éjection et ladite cavité d'encre commune ; et
- un substrat supérieur (1) et un substrat inférieur (3) fixés audit substrat en silicium, en formant ainsi ladite chambre d'éjection avec ladite cavité d'encre et lesdits orifices, et munis d'électrodes (31, 31a, 31b) placées en face desdits diaphragmes (5, 5a, 5b), dont chacune forme la partie de fond desdites portions concaves, un espace (c) étant prévu entre les diaphragmes (5, 5a, 5b) et le substrat inférieur (3).
2. Dispositif d'enregistrement à jet d'encre selon la revendication 1, caractérisé en ce qu'au moins un desdits substrats, supérieur et inférieur, est d'un type vitreux.
3. Dispositif d'enregistrement à jet d'encre selon l'une ou l'autre des revendications 1 et 2, caractérisé en ce que lesdites électrodes (31) sont recouvertes d'un film isolant (34).

4. Dispositif d'enregistrement à jet d'encre selon une quelconque des revendications précédentes, caractérisé en ce que ledit substrat en silicium est constitué par des premier et deuxième substrats de silicium (2a, 2b) fixés l'un à l'autre pour former ladite chambre d'éjection, et caractérisé en outre en ce que les substrats supérieur et inférieur sont munis d'électrodes (31a, 31b) placées face aux diaphragmes (5a, 5b) en laissant un espace entre elles et ces diaphragmes.
5. Dispositif d'enregistrement à jet d'encre selon une quelconque des revendications précédentes, caractérisé en ce que chacun desdits diaphragmes (5) est de la forme d'un rectangle ou d'un carré et est supporté par des rainures (27) analogues à des soufflets formées sur deux côtés opposés ou sur les quatre côtés dudit rectangle ou carré.
6. Dispositif d'enregistrement à jet d'encre selon une quelconque des revendications 1 à 4, caractérisé en ce que chacun desdits diaphragmes (5) est de la forme d'un rectangle ou d'un carré, dont un côté est supporté en porte-à-faux, et on utilise de l'encre isolante pour ladite encre.
7. Dispositif d'enregistrement à jet d'encre selon une quelconque des revendications précédentes, caractérisé en ce que lesdites électrodes (31) sont prévues de manière qu'une paire de première et deuxième électrodes soient formées pour chacun desdits diaphragmes (5), ladite première électrode (31) étant disposée à l'intérieur d'une chambre de vibration (9) prévue juste sous ledit diaphragme (5), ladite deuxième électrode (33) étant disposée à l'extérieur de ladite chambre de vibration (9), et en ce qu'un circuit oscillant est prévu de manière à appliquer alternativement auxdites deux électrodes (31, 33) des impulsions électriques opposées entre elles en polarité.
8. Dispositif d'enregistrement à jet d'encre selon une quelconque des revendications 1 à 6, caractérisé en ce que deux électrodes (31) sont disposées à l'intérieur d'une chambre de vibration (9) prévue adjacente à chaque diaphragme (5).
9. Dispositif d'enregistrement à jet d'encre selon une quelconque des revendications 1 à 6, caractérisé en ce que des électrodes métalliques sont prévues respectivement dans lesdits diaphragmes de façon correspondante de manière que lesdites électrodes métalliques soient placées face auxdites électrodes (31).
10. Dispositif d'enregistrement à jet d'encre selon l'une ou l'autre des revendications 7 et 8, caractérisé en ce que lesdites chambres de vibration (9) commu-

niquent avec l'air à travers des passages d'air.

11. Dispositif d'enregistrement à jet d'encre selon une quelconque des revendications 1, 2, 3, 4, 7, 8 ou 9, caractérisé en ce que lesdites électrodes (31, 31a, 31b) sont prévues respectivement dans des portions concaves (25, 29) desdits substrats, le substrat en silicium ou le substrat inférieur (2, 3).
12. Dispositif d'enregistrement à jet d'encre selon l'une ou l'autre des revendications 1 et 2, caractérisé en ce que lesdites buses (4) sont agencées à des intervalles égaux dans une portion d'extrémité dudit substrat en silicium (2).
13. Dispositif d'enregistrement à jet d'encre selon une quelconque des revendications 1 à 10, caractérisé en ce que lesdites ouvertures de buses (4) sont agencées à des intervalles égaux dans le substrat extrême supérieur (1), chacune au-dessus d'une chambre d'éjection respective (6).
14. Procédé pour produire une tête à jet d'encre pour un dispositif d'enregistrement à jet d'encre, le procédé comprenant les phases consistant à :

graver un substrat en silicium (2) anisotropiquement sur une première surface de ce substrat pour former une pluralité de portions concaves (22, 24), dont les bords délimitent une pluralité de chambres d'éjection (6) ayant des parois de fond qui servent de diaphragmes (5), une cavité commune (8) et des rainures (23) servant d'entrées d'encre (7), l'agencement étant tel qu'une pluralité desdites rainures (23) établissant la communication entre une extrémité de chaque chambre d'éjection (6) et la cavité commune (8) ;

fixer un premier substrat isolant à ladite première surface du substrat en silicium (2), et former des électrodes (31) sur une première surface d'un deuxième substrat isolant (3), et fixer ledit deuxième substrat isolant (3) à la surface du substrat en silicium (2) qui est à l'opposé de ladite première surface de manière que lesdites électrodes (31) soient placées face auxdits diaphragmes (5) en laissant un espace (c) entre elles et ces diaphragmes.

15. Procédé selon la revendication 14, comprenant en outre la phase consistant à graver le substrat en silicium (2) anisotropiquement sur sa surface qui est à l'opposé de ladite première surface, en coïncidence avec lesdites chambres d'éjection (6) pour former des chambres de vibration (9) au-dessous desdits diaphragmes (5).

16. Procédé selon la revendication 14 ou la revendica-

tion 15, dans lequel ledit deuxième substrat isolant (3) a une deuxième portion concave (9) sur laquelle lesdites électrodes (31) sont formées.

17. Procédé selon une quelconque des revendications 14 à 16 comprenant en outre la phase consistant à former une couche isolante (34) sur lesdites électrodes (31). 5
18. Procédé selon une quelconque des revendications 14 à 17, dans lequel ladite phase consistant à graver ladite première surface du substrat en silicium anisotropiquement comprend en outre la formation de rainures de buses (21) agencées à des intervalles égaux sur ladite première surface en communication avec lesdites portions concaves (22) et qui coupent un bord dudit substrat en silicium (2) au droit des ouvertures de buses (4). 10 15
19. Procédé selon une quelconque des revendications 14 à 17, dans lequel les ouvertures de buses (4) sont agencées à des intervalles égaux dans ledit premier substrat isolant (1), chaque ouverture de buse (4) étant placée au-dessus d'une chambre d'éjection (6) respective. 20 25
20. Procédé selon une quelconque des revendications 14 à 17, dans lequel ledit deuxième substrat isolant (3) est fixé à la surface du substrat en silicium (2) qui est à l'opposé de ladite première surface par une fixation anodique. 30
